

Meteorology Challenge

1. There is weather on Earth because water evaporates, forming clouds that produce rain, creating weather. This is part of the water cycle system.
2. The energy that the weather causes comes from the sun, which evaporates water. This then turns the water into clouds, creating weather.
3. Climate is the temperature of places throughout the year, and weather is if there are clouds and what they are doing. This makes them separate but still similar.
4. Convection is where warm air or water moves to cooler areas, and convergence is where two wind or water currents converge as they hit each other. Worldwide winds do both of these things as they move around.
5. Air does have mass; it is just that it has little enough mass that it floats in air, because air is air. I would prove this by putting some air in water and because the mass is lighter but still existent it would float. You could also put in helium to make it sink
6. Heating and cooling water make it expand and contract. As the water expands, it becomes less dense and vice versa.
7. I know the atmosphere exerts pressure on me because, while hard to discern on its own, it is easy to feel a few feet down in water. It also becomes much more noticeable if you go down into canyons or up on mountains.
8. Different materials have different properties, and some retain energy better than others. This is called conductivity, I think.
9. The sky refracts light, and because it bends so much, we only see the high-energy blue and purple light, so that is what we see.

10. Warmer air can hold more water vapor because water molecules move faster, making it less likely to condense and allowing it to stay in warmer air longer. This allows more water to be present in warmer air.
11. Humidity is the amount of water in the air. It is measured by Taking air and determining the amount of water in it.
12. In cloud formation, three of the steps are evaporation, convergence, and condensation. This allows the water vapor to gather with other water vapor to become clouds.
13. Large towering clouds called colomonmomonbisssbsin create lightning. This is scary and is is bad to be around during colomonmomonbissibnibin clouds. Thunder and lightning are probably Zeus's fault.
14. The high is the max temperature it will reach and the low is the minimum temperature. The weather expected to be found in each is very limited because nobody really expects the weather report to be that accurate.
15. Argon, oxygen, carbon dioxide, and other ghg are found in the atmosphere. This is because humans don't know how to capture cow farts.
16. There is more pressure lower down in the world, especially under y level 9, because that is where deepslate starts to spawn. The temperature is also warm on the ground (because of earths core), and warm in the sky (because sun), but quite cold just off the ground so overall, its cold in the sky.
17. El nino means the boy and the other means the girl. This was created to it did not sound sexist that there was only one.
18. Tornados are formed when scary wind attacks itself, and then starts spinning. This can be scary depending on if you can see it.

19. Hurricanes form when wind attacks itself but it is also scary. It is also when wind be spinning in circles.

20. Global warming is caused by cows fart too much and humans eating too many cows. Then the cow farts are angry so they try to strangle the earth making the earth hot because it is an awkward situation.

Extra credit: Hurricanes are called bad in the Indian Ocean, scary in the Atlantic Ocean, and terrifying in the Pacific Ocean. This is especially true for people who live in the middle of the Pacific Ocean.
